Patients with malignant disease have an increasing incidence of bone metastases, which are the most common cause of morbidity in elderly patients. Patients with bone metastases have a poor quality of life, with increased risk of fracture and impairment of activities of daily living. The aim of therapy is to prevent complications, to provide pain relief and to prolong survival time. For prevention of skeletal-related events, bisphosphonates are the gold standard. Denosumab, with a different mechanism of action, can be used in cancer patients with high risk of skeletal-related events. RANK ligand inhibitors are emerging as new agents. A number of other agents have demonstrated activity in clinical trials, including zoledronic acid, pamidronate, ibandronate, ibandronic acid, zoledronic acid with bisphosphonates, denosumab with zoledronic acid, interferon, and denosumab with pamidronate. Other treatment options are discussed, including non-hormonal anti-osteoclast therapy, ablation of bone metastases by surgery, radiotherapy, or targeted therapy. The purpose of this paper is to review the data on the use of the different agents in the clinical practice.
